

Post-epidemic burnout under logistic susceptible recovery

Post-epidemic boundary-layer probability; $K = 10,000$; $I(0) = 1$; $m = \max[1, \text{round}(K y_{BL})]$

The deterministic major-epidemic path starts at $S(0)=K-1$, $I(0)=1$.

This conditional post-epidemic probability excludes early stochastic extinction. Grey cells denote failed calculations.
